Ising Model & Monte Carlo method

Yingsheng Huang

Ising Model:

- Hamiltonian of the system:

$$H(\sigma) \overset{====}{} -J\sum_{\langle ij\rangle}\sigma_i\sigma_j - h\sum_j \sigma_j$$
$$\overset{h=0}{====} -J\sum_{\langle ij\rangle}\sigma_i\sigma_j$$

  h is the external magnetic field (for simplicity we now consider $h = 0$), and $J > 0$ which means it's ferromagnetic. (And it's reasonable to consider the lowest energy state is when the spins are all $+1$.)

- Total Energy at configuration $\{\sigma_i\}$:

$$E_{\{\sigma_i\}} = -J\sum_{\langle ij\rangle}\sigma_i\sigma_j - h\sum_j \sigma_j$$

- Spin state σ_i is differed by

$$\sigma_i = \begin{cases} +1 \\ -1 \end{cases}$$

- Configuration probability:

$$P_\beta(\sigma) = \frac{e^{-\beta H(\sigma)}}{Z_\beta}$$

  where $\beta = (k_B T)^{-1}$ and Z_β is the partition function.

- Partition function:

$$Z_\beta = \sum_\sigma e^{-\beta H(\sigma)}$$

Mento Carlo Method (Metropolis Method):

- Given L^d lattice point. (For instance $d = 1$, which means 1-d Ising model.)

  (1)Give a initial state, and calculate its energy. Calculate the magnetic dipole and get the phase transition point.
